

September 28, 2018 Indonesia (M 7.5) 10:02:43 UTC / 18:02:43 at epicenter **University of Kentucky Kentucky Seismic and Strong Motion Network**

The September 28, 2018 magnitude 7.5 earthquake near Palu, Indonesia occurred near a microplate (minor tectonic plate) boundary within the Sunda tectonic plate. Very strong shaking was experienced from this earthquake due to its magnitude and shallow depth (10 km) and its proximity to populated areas, including Palu (population of more than 335,000), ~40 km to the south of the modeled causative fault. Soil liquefaction was induced and widespread destruction and damage, especially in low-lying and coastal areas, occurred. The shallow earthquake also generated a tsunami. More than 1,200 deaths have been reported from this earthquake.

This mechanism indicates predominantly

strike-slip faulting. The aftershock distribution clarifies that the 350° striking plane ruptured in the earthquake.

Slip (rupture) along Fault

Fault rupture occurred for more than 30s and slip (i.e. displacement) of up to 8 m may have occurred, at a location 20 m down the fault plane.

CUSSO "P" marks arrival time of primary body-wave in Irvine, Ky. Peak up-and-down surface-wave displacement recorded at EK20 is labeled.

KSSMN Seismic Stations Stations with seismograms are labeled by name.
