Right now, clinical researchers are looking for people age 60 to 75 who may have a higher risk of developing Alzheimer’s disease later in life. This risk is because of a certain gene (called APOE4) that may or may not be in your DNA.

This study is investigating medications that could advance doctors’ understanding of how to potentially prevent the onset of Alzheimer’s disease. By joining this study, you could help impact the future of medicine. Qualified participants may also receive genetic counseling, study medication, and study-related care.

To qualify for this study you must:
• Be 60 to 75 years of age
• Have normal memory and thinking ability
