# CONSTELLATION LESSON 

Name $\qquad$ Time $\qquad$

## How can I locate things in the sky?

## Stars and Constellations

We will begin observing with a tour of the night sky. This activity is intended to introduce you to the stars, planets, and constellations in the sky. It also introduces the concept of angular distances and how to make crude angular measurements.

1) Identifying Stars and Constellations - You will use your skymap to locate various constellations and stars. On the skymap the various stars are labeled. WHEN ASKED TO DRAW CONSTELLATIONS, DRAW WHAT YOU SEE IN THE SKY, NOT WHAT IS ON THE SKYMAP. In order to begin using the skymap you will need to know the direction that you are facing. Locate North, South, East and West.

You will need to measure some angles in this activity. For this we will use the Fist Method. If you make a fist and hold it at arms length, with your elbow extended, then the angle that your fist covers is roughly 10 degrees.

Find and draw in the space below Ursa Minor, Draco, and Ursa Major. Label on the drawing the star, Polaris (The North Star).

Next find and draw Leo, Virgo and Bootes. Label the stars Regulus, Spica and Arcturus.

Next find and draw Cygnus, Lyra, Hercules, and the Corona Borealis and label the stars, Deneb, Vega, and Altair. (Note: These three stars make a large triangle on the sky which is called the Summer Triangle.)

Finally find and draw Scorpius and Sagittarius, and label the star Antares.

2) Estimating Angular distance - Use the fist technique to measure the angular distances between the following stars. We will be checking your results later so be as precise as possible. Each member of the group should make the measurement and then each group should average the measurements to get the best result.

| Objects | Angle \#1 <br> (degrees) | Angle \#2 <br> (degrees) | Angle \#3 <br> (degrees) | Angle \#4 <br> (degrees) | Ave. Angle <br> (degrees) |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Northern <br> Horizon to <br> Polaris |  |  |  |  |  |
| Vega to <br> Deneb |  |  |  |  |  |
| Altair to <br> Arcturus |  |  |  |  |  |
| Polaris to <br> Antares |  |  |  |  |  |

Which measurement above do you think is the most uncertain? Why?

Which measurement has the greatest spread between the values found by each person?

Do you think the average value is the "best" value? Why or why Not?

Moon Observations -- Observing the terminator
The terminator is the name of the imaginary line between the bright portion of the Moon and the dark portion. If you remember that the Moon looks like a circle, then there is a dark portion and light portion of the Moon. The terminator is the line that separates the dark and bright portions.

You now know where to find the constellations of Gemini and Taurus. On the days when the Moon is located near Gemini and Taurus pay special attention to the shape of the terminator. In your Moon Journal carefully draw the Moon and pay special attention to the terminator. When you draw the Moon also draw the stars near the Moon that are in Gemini or Taurus.

On these days does the terminator look like a straight line? Or does it curve? If it curves does it curve to the West or does it curve to the East? Be careful to draw the terminator on your Moon exactly as it looks in the sky.
